Quiz: True or False?

Alzheimer’s disease can not be diagnosed without an autopsy of brain tissue.

Today there are medications that cure Alzheimer’s disease.

Alzheimer’s symptoms do not usually appear until 20 or more years from the onset.

Brain tissue does not regenerate.
Objectives

Learn epidemiology & pathogenesis of Alzheimer’s Disease.

Understand the impact of uncontrolled diabetes mellitus (DM) on the pathology of Alzheimer’s.

Recognize the importance of partnership between Alzheimer’s Association and DM programs.

Evaluate appropriate Alzheimer’s screening in clinical practice.

Dementia

Dementia is a set of symptoms with many causes.

Some forms of dementia, such as a drug interaction or a vitamin deficiency, are actually reversible or temporary.

https://www.alzheimers.net/difference-between-alzheimers-and-dementia/

Possible Causes of Dementia

- medication side effects
- chronic alcoholism
- tumors or infections in the brain
- blood clots in the brain
- vitamin B12 deficiency
- some thyroid, kidney, or liver disorders
- stroke
- Parkinson’s disease
- Sleep disturbances

National Institute on Aging Last Updated: May 4, 2017
https://vivacare.com/nwn/HealthTopic/Alzheimers_Disease_Overview
• Age major risk factor
• Damaged proteins
• Genetics (family history of Alzheimer’s)
• Neuronal energy failure
• Neuro-inflammation
• Vascular disease

Alzheimer’s disease (AD) is the most common cause of dementia and one of the leading sources of morbidity and mortality in the aging population

Alzheimer’s is not a reversible disease. It is degenerative and incurable at this time.

https://www.alzheimers.net/difference-between-alzheimers-and-dementia/

5.5 million Americans living with Alzheimer’s Disease
Costs

- $259 billion in 2017
- Between 2017 and 2013 $7.7 trillion in health care costs.

Diagnosis

Currently Dx is made 90% of the time using:
- Questions about patient's health, past medical problems and ability to carry out daily tasks.
- Cognitive tests including memory, problem solving, attention level and language.
- Medical tests: brain scans

Pathogenesis

- The neuropathological hallmarks of Alzheimer disease include diffuse and neuritic extracellular amyloid plaques in brain that are frequently surrounded by dystrophic neurites and intraneuronal neurofibrillary tangles.
Diagnostic Markers

MRI (magnetic resonance imaging)
PET scan (positron emission tomography to measure amyloid in brain)
Spinal Cord Fluid
Glucose Metabolism in the Brain
Genetic Markers

Genetics Markers

- APO-E 4 increases risk for Alzheimer’s
- APO-E gene determines the type of protein produced to bind & transport fat particles to the liver.
- APO-E has three possibilities, 2,3,4 with APO-E3 most common.
Inside the Brain

In the Alzheimer brains:
- The cortex shrivels up, damaging areas involved in thinking, planning and remembering.
- Shrinkage is especially severe in the hippocampus, an area of the cortex that plays a key role in formation of new memories.
- Ventricles (cerebrospinal fluid-filled spaces within the brain) grow large.

**Can Brain Cells Regenerate?**

- Conventional medical wisdom has held that people are born with all of the brain cells they will ever have, and once they are gone, they are permanently gone.
- Now, however, scientists have found that cells in the region of the brain responsible for memory and learning (hippocampus) are capable of being regenerated in a laboratory.
- Although there are currently no practical applications for this new finding, it could have implications in the future for the treatment of neurodegenerative diseases and brain trauma.

**Do Brain Cells Regenerate?**

University of Pennsylvania in 2010 reported that aerobic exercise among 120 older adults increased the actual size of the hippocampus by two percent and effectively reversed the aging-related cell loss by one to two years.

Glucose Levels and Risk of Alzheimer’s

“It may be that with the brain, every additional bit of blood sugar that you have is associated with higher risks. It changes how we think about thresholds, how we think about what is normal, what is abnormal.”

Published 2013, New England Journal of Medicine

DOI: 10.1056/NEJMoa1215740

Pharmaceutical Targets
- APOE (apoipoprotein E): genetic risk factor for late-onset. Target for AADF-funded scientists developing drugs to modify risk.
- Inflammation & Vascular: Target for drugs to protect against injury-induced inflammation.

Research with Victoza
- King’s College London, University of Cambridge, University of Southampton, University of Bristol, Birmingham University, University of Brighton, St Georges University of London evaluating the novel diabetic drug, liraglutide in the treatment of Alzheimer’s disease (ELAD study) 2017.
- Cost of Victoza: $800-$1,000. Some insurances pays 50% Manufactory’s coupon

Research with Brain Ketones Metabolism
- Ketogenic Interventions in Alzheimer’s: Found that 40% decrease glucose metabolism in some area of the brain.
- Recent studies show the brain is able to use ketones in place of glucose.
- A Ketogenic Diet is being tested by Dr. Swerdlow, University of Kansas Alzheimer’s Disease Center.
Breaking News

February 2018

• Enzyme, BACE1 inhibitor shown to “completely” reverse build up of beta-amyloid plaque in the brain.
• Study on mice only by scientists at Cleveland Clinic Research Institute in Ohio.
• Further study needed.

Recent Findings

1. Possible that low Serotonin is involved in Alzheimer’s.
2. Potential use of extremely low frequency electromagnetic waves to treat Alzheimer’s.

Prevention is “Brain Health”

- The American Heart Association and American Stroke Association have issued an advisory on maintaining optimal brain health throughout life.

- After reviewing 182 scientific studies of brain and heart health, they issued a seven step plan for helping to keep the brain in top working order and to keep Alzheimer’s at bay in old age.

- The advisory reflects a growing body of evidence that what’s good for the heart is good for the brain.

Steps to brain health

Diet: Mediterranean, Dash

Don’t smoke: Smoking can damage blood vessels throughout the body, including in the brain.

Exercise: Regular physical activity is good for the heart and the brain.

Healthy weight. Obesity at midlife is a risk factor for Alzheimer’s disease and other forms of dementia.

Blood pressure. Below 120/80, the same risk factors for stroke are also risk factors for Alzheimer’s disease.

Maintain a healthy cholesterol. High cholesterol is a known risk factor for Alzheimer’s.

Control blood sugar: Type 2 diabetes, a risk factor for Alzheimer’s disease.

Add Brain Games to Your Daily Routine

Brain Training and Dementia

A newly published paper shows that one particular type of brain training exercise—called “speed of processing training” in the study—cut the long-term risk of dementia by 29%.

These new results are from a gold-standard randomized controlled clinical trial—and allow scientists for the first time to say that doing the brain training directly reduces the risk of dementia.

The Self-Administered Gerocognitive Exam (SAGE) was developed by Ohio State University College of Medicine, Department of Neurology. The test is a cognitive screening instrument used to identify Mild Cognitive Impairment (MCI) and early dementia. The test is self-administered, so people questioning their own cognitive abilities can take the exam privately.
